# Intercontinental Bearing Supply Company, Inc. 

Catalog of
Precision Miniature and Thin Section Ball
Bearings

Intercontinental Bearing Supply Co., Inc.

Founded in 1981, Intercontinental Bearing Supply Co. has acquired a leadership position as a supplier of high quality bearing products to the OEM and Distributor marketplace.

Our position of leadership is maintained through:
A total commitment to our customers complete satisfaction We acknowledge our customer as our reason for being

Significant investments in high quality inventories Proven, reliable brand named products

Staying at the leading edge of new bearing technologies Technology keeps our customers ahead of the competition

The application of advanced clean room design \& practice
Certified annually to Federal Standard 209, and factory authorized by both NMB \& NHBB
Advanced computer application and integration Real time response and integration in everything we do

Acquisition and continuous training of dedicated personnel
Knowledge and proficiency our customers rely on
ISO 9001 Certification
Accountability of operations \& quality control
A commitment to continuous improvement Embraced and accepted as a never ending goal

Strong vendor alliances and relationships Representing only the very best in quality bearing products

The employees and management of IBSCO are proud of our past and present accomplishments, and we look forward to the continued growth of strong customer relationships based on mutually beneficial business strategies.

Randall Burton, President

## Table of Contents

Products
Inch Series Ball Bearings, Radial Design
Open \& Shielded, Unflanged ..... 1
Open \& Shielded, Flanged ..... 2
Extended Inner Ring Open \& Shielded, Unflanged ..... 7
Extended Inner Ring Open \& Shielded, Flanged ..... 8
Full Compliment Open \& Shielded, Unflanged ..... 9
Full Compliment Open \& Shielded, Flanged ..... 10
Tapered O.D. Shielded, Flanged ..... 11
"R" Series, Open \& Shielded, Unflanged ..... 12
"R" Series, Open \& Shielded, Flanged ..... 12
High Speed, Open \& Shielded, Phenolic Retainer ..... 18
Thin Section, Open \& Shielded ..... 21
Thin Section, Open \& Shielded, Phenolic Retainer ..... 21
Torque Tube, Open \& Shielded, Phenolic Retainer ..... 24
Inch Series Ball Bearings, Angular Contact Design
High Speed, Open \& Shielded, Phenolic Retainer ..... 17
Thin Section, Open \& Shielded, Phenolic Retainer ..... 22
Torque Tube, Open \& Shielded, Phenolic Retainer ..... 23
Metric Series Ball Bearings, Radial Design
Radial Open \& Shielded, Unflanged ..... 13
Radial Open \& Shielded, Flanged ..... 14
High Speed, Radial Open \& Shielded, Phenolic Retainer ..... 18
Thin Section, Open \& Shielded, Unflange.d ..... 25
Thin Section, Open \& Shielded, Flanged ..... 26
Metric Series Ball Bearings, Angular Contact Design
High Speed, Open \& Shielded, Phenolic Retainer ..... 17
Ball Thrust ..... 20
Engineering
Radial and Axial Play ..... 28
Raceway Curvature, Contact Angle ..... 29
Free Angle of Misalignment ..... 29
Materials ..... 30
Shields and Seal types ..... 31
Cages ..... 32
Lubrication ..... 33
Lubrication Methods ..... 35
Operating Speed. ..... 35
Preload and Duplex Ball Bearings ..... 36
Assembly and Fitting Procedure ..... 38

## Miniature - Flanged

Notes:

1. Basic numbers shown include code " $S$ " for ASI 440C or DD stainless steel. If chrome alloy SAE 52100 is desired, delete the " S " prefix code.
2. See page 40 for ABEC tolerances.
3. $r=$ Maximum shaft or housing fillet radius that bearing corners will clear.

## METRIC SERIES

## Miniature - Flanged

Notes:

1. Basic numbers shown include code " $S$ " for ASI 440C or DD stainless steel. If chrome alloy SAE 52100 is desired, delete the " S " prefix code.
2. See page 40 for $A B E C$ tolerances.
3. $r=$ Maximum shaft or housing fillet radius that bearing corners will clear.
4. Inch dimensions for reference only.

## METRIC SERIES

## Miniature - Flanged

Notes:

1. Basic numbers shown include code " $S$ " for ASI 440C or DD stainless steel. If chrome alloy SAE 52100 is desired, delete the " S " prefix code.
2. See page 40 for ABEC tolerances.
3. $r=$ Maximum shaft or housing fillet radius that bearing corners will clear.
4. Inch dimensions for reference only.

## Miniature - Radial

## Notes:

1. Basic numbers shown include code "S" for ASI 440C or DD stainless steel. If chrome alloy SAE 52100 is desired, delete the "S" prefix code.
2. See page 40 for ABEC tolerances.
3. See page 35 for $f / n$ vs. cage, lubricant and ring rotation.
4. $r=$ Maximum shaft or housing fillet radius that bearing corners will clear
Please consult IBSCO for machined cage options.
Also available in flanged version.

High Speed Specialty Bearings (HSSB) have been developed for applications that require precise running accuracy and high speed capability, with the option of autoclavability. These bearings are widely used in critical Dental/Medical Applications, although they are ideally suited for any high speed (up to 500,000 RPM) application. The design of these bearings incorporates the advantages of super precision tolerancing, balanced design, raceway super finishing, and a variety of retainer options. While the sizes listed in this section represent current production sizes, almost any size in this catalog under 1.1250 O.D.can be produced to take advantage of the operating characteristics of the HSSB's.

## INCH SERIES

## Torque Tube - Abec 5\&7- Phenolic Retainer

Notes:

1. Basic numbers shown include code " S " for ASI 440C stainless steel. If chrome alloy SAE 52100 is desired, delete the " S " prefix code.
2. See page 40 for ABEC tolerances.
3. $r=$ Maximum shaft or housing fillet radius that bearing corners will clear.
4. Metric dimensions for reference only.

* Speed Rating 1 - No closures with oil
* Speed Rating 2 - Shielded with grease

Double Shielded bearing uses thin section phenolic retainer, reducing speed rating.
Single Shielded construction is available with full section phenolic retainer (w/oil) maintaining same speed rating as with no closures.

## Designing To Lower Total Cost

The majority of applications can be effectively handled using a "standard bearing". A "standard bearing", in this case, refers to bearing that is in such worldwide demand that large volumes are produced. This virtually guarantees continuity of supply while assuring pricing benefits for the O.E.M. Selection of a "standard bearing" at the design stage cannot be over emphasized. The considerations necessary to design for lower cost include:

- Dimensional size
- Material type
- Lubrication
- Enclosures
- Cage style (retainer)
- Manufacturability
- Assembly and fits
- Packaging
- Quality requirements

Although different designers may vary in their approach to bearing selection, the following is one method that works well.

- Establish operating, environmental and performance requirements such as load, speed, noise, etc.
- Select a bearing configuration to meet the above requirements.

Some examples of configuration types are:

1. Flanged or unflanged
2. With or without a snap ring
3. Ball complement/size

- Determine bearing envelope to accommodate shaft and housing requirements. This step is critical to cost. It is quite often more cost-effective to design the housing and shaft around a popular bearing size than vice versa.
- Specify enclosures as necessary. Be careful not to specify a more expensive enclosure than necessary to perform properly in the application.
- Specify required cage type. For the majority of cases, the standard cage for a particular chassis size will be adequate.
- Determine the bearing noise rating that is required for the application. For most cases, our standard "No Code" noise rating will provide quieter operation than most other components in the system. For extremely noise sensitive applications, a quieter noise rating can be specified.
- Determine degree of precision needed to achieve the performance requirements (ABEC Level).
Do not over estimate what is truly necessary to achieve the desired performance.
- Determine the radial play specification. The standard radial play specification for a chassis size will be adequate to handle normal press fits, moderate temperature differentials and normal speeds.
- Determine lubrication requirements. This should include lubrication characteristics and the amount of lubricant needed. This is a critical step in the performance and reliability of the bearing in the application.

Care should be taken throughout this process with respect to both cost and performance. The key in designing for the lowest total cost is to involve the Sales and Application Engineering staff early in the selection process. Costs will be impacted greatly if the envelope dimensions are not given consideration at the time of bearing selection. IBSCO offers an experienced Sales and Engineering staff to help in the design and selection process insuring your success.

## Raceway, Track Diameter, and Track Radius

The raceway in a ball bearing is the circular groove formed in the outside surface of the inner ring and in the inside surface of the outer ring. When the rings are aligned, these grooves form a circular track that contains the ball set.

The track diameter and track radius are two dimensions that define the configuration of each raceway. Track diameter is the measurement of the diameter of the imaginary circle running around the deepest portion of the raceway, whether it be an inner or outer ring. This measurement is made along a line perpendicular to, and intersecting, the axis of rotation. Track radius describes the cross section of the arc formed by the raceway groove. It is measured when viewed in a direction perpendicular to the axis of the ring. In the context of ball bearing terminology, track radius has no mathematical relationship to track diameter. The distinction between the two is shown in Figure 1.

## Radial and Axial Play

Most ball bearings are assembled in such a way that a slight amount of looseness exists between balls and raceways. This looseness is referred to as radial play and axial play. Specifically, radial play is the maximum distance that one bearing ring can be displaced with respect to the other, in a direction perpendicular to the bearing axis, when the bearing is in an unmounted state. Axial play, or end play, is the maximum relative displacement between the two rings of an unmounted ball bearing in the direction parallel to the bearing axis. Figure 2 illustrates these concepts.

Since radial play and axial play are both consequences of the same degree of looseness between the components in a ball bearing, they bear a mutual dependence. While this is true, both values are usually quite different in magnitude.

In most ball bearing applications, radial play is functionally more critical than axial play. If axial play is determined to be an essential requirement, control can be obtained through manipulation of the radial play specification. Please consult with Application Engineering if axial play ranges for a particular chassis size are required.

Figure 1. The distinction between track radius and track diameter (inner ring).

Some general statements about Radial Play:

1. The initial contact angle of the bearing is directly related to radial play- the higher the radial play, the higher the contact angle.
2. For support of pure radial loads, a low level of radial play is desirable; where thrust loading is predominant, higher radial play levels are recommended.
3. Radial play is affected by any interference fit between the shaft and bearing I.D. or between the housing and bearing O.D. See the Assembly and Fitting Procedure section on page 38 for more details.

Also, since the actual play remaining after assembly of the complete device is the important condition, the radial play specification for the bearing itself must be modified in accordance with the discussion on page 38. If the system spring rate is critical, or if extremes of temperature or thermal gradient will be encountered, consult with our Engineering Department prior to design finalization.

Figure 2. The distinction between radial play and axial play.

Definitions

Table Of Contact Angles

| Ball Size <br> $D_{w}$ | RADIAL PLAY CODE <br> P25 |  |
| :--- | :---: | :---: |
| .025 | $18^{\circ}$ | $24^{\circ}$ |
| $1 / 32 \& 0.2^{\circ}$ |  |  |
| 1 mm | $16^{\circ} 12^{\circ}$ | $22^{\circ}$ |
| $3 / 64$ | $14^{1} 12^{\circ}$ | $20^{\circ}$ |
| $1 / 16$ | $14^{\circ}$ | $18^{\circ}$ |
| $3 / 32$ | $12^{\circ}$ | $16^{\circ}$ |
| $1 / 8$ | $9^{\circ} 1 / 2^{\circ}$ | $13^{\circ}$ |
| $9 / 64$ | $12^{\circ} 12^{\circ}$ | $17^{\circ}$ |
| $5 / 32$ | $12^{\circ}$ | $16^{\circ}$ |
| $3 / 16$ | $11^{\circ}$ | $15^{\circ}$ |
|  | $10^{\circ}$ | $14^{\circ}$ |

The contact angle is given for the mean radial play of the range shown i.e., for P25 (.0002" to .0005") - contact angle is given for .00035". Contact angle is affected by race curvature. For your specific application, contact IBSCO Engineering.

## Raceway Curvature

Raceway curvature is an expression that defines the relationship between the arc of the raceway's track radius and the arc formed by the slightly smaller ball that runs in the raceway. It is simply the track radius of the bearing raceway expressed as a percentage of the ball diameter. This number is a convenient index of "fit" between the raceway and ball. Figure 3 illustrates this relationship.

Track curvature values typically range from approximately 52 to 58 percent. The lower percentage, tight fitting curvatures are useful in applications where heavy loads are
encountered. The higher percentage, loose curvatures are more suitable for torque sensitive applications. Curvatures less than 52 percent are generally avoided because of excessive rolling friction that is caused by the tight conformity between the ball and raceway. Values above 58 percent are also avoided because of the high stress levels that can result from the small ball-to-raceway conformity at the contact area.

## Contact Angle

The contact angle is the angle between a plane perpendicular to the ball bearing axis and a line joining the two points where the ball makes contact with the inner and outer raceways. The contact angle of a ball bearing is determined by its free radial play value, as well as its inner and outer track curvatures.

The contact angle of thrust-loaded bearings provides an indication of ball position inside the raceways. When a thrust load is applied to a ball bearing, the balls will move away from the median planes of the raceways and assume positions somewhere between the deepest portions of the raceways and their edges. Figure 4 illustrates the concept of contact angle by showing a cross sectional view of a ball bearing that is loaded in pure thrust.

## Free Angle and Angle of Misalignment

As a result of the previously described looseness, or play, which is purposely permitted to exist between the components of most ball bearings, the inner ring can be cocked or tilted a small amount with respect to the outer ring. This displacement is called the free angle of the bearing, and corresponds to the case of an unmounted bearing. The size of the free angle in a given ball bearing is determined by its radial play and track curvature values. Figure 5 illustrates this concept.

For the bearing mounted in an application, any misalignment present between the inner and outer rings (housing and shaft) is called the angle of misalignment. The misalignment capability of a bearing can have positive practical significance because it enables a ball bearing to accommodate small dimensional variations which may exist in associated shafts and housings. A maximum angle of misalignment of $1 / 4^{\circ}$ is recommended before bearing life is reduced. Slightly larger angles can be accommodated, but bearing life will not be optimized.

Figure 3. The relationship of track radius to ball diameter.

Figure 5. Free angle of the bearing.

## ENGINEERING

Definitions

## Bearing Materials

## Chrome Steel

Bearing steel used for standard ball bearing applications in uses and in environments where corrosion resistance is not a critical factor.

## 52100 or Equivalent

The most commonly used ball bearing steel in such applications is SAE 52100 or its equivalent. Due to its structure, this is the material chosen for extreme noise sensitive applications.

## Stainless Steel

## DD400 ${ }^{\text {TM }}$

0.7\% C; 13\% Cr

A 400 series Martensitic stainless steel combined with a heat treating process that was exclusively developed by NMB's parent company. Miniature and instrument bearings manufactured from "DD" Martensitic stainless steel, or "DD Bearings", meet the performance specifications of such bearings using AISI 440C Martensitic stainless steel, and it is equal to or superior in hardness, superior in low noise characteristics, and is at least equivalent in corrosion resistance. These material characteristic advantages make for lower torque, smoother running, and longer life bearings.

## AISI 440C

1\% C, 17\% Cr, .5\% Mo
A hardened, stainless steel suitable for applications which require corrosion resistance at room to mid-hot temperature range; the standard choice for a wide range of military and commercial applications.

## Alternate Ball Material

## Cerbec® Bearing Components

Silicon Nitride
An extremely hard non-metallic material suitable for speeds up to 2 million $d N$ with reduced skidding. This material is corrosion resistant, $40 \%$ lighter than steel and non-magnetic. Silicon nitride has a modulus of elasticity $50 \%$ greater than steel, therefore it resists corrosion and galling.

| Material | Specification | Attributes | Room Temp. <br> Hardness (Rc) |
| :---: | :---: | :---: | :---: |
| Silicon <br> Nitride | CERBEC <br> Silicon <br> Nitride | Extended life, lower torque, <br> light weight, higher stiffness | $>78$ |

## Definitions

Shields and seals are necessary to provide optimum ball bearing life by retaining lubricants and preventing contaminants from reaching central work surfaces. IBSCO can supply ball bearings with several types of protective closures that have been designed to satisfy the requirements of most applications. Different types of closures can be supplied on the same bearing and nearly all are removable and replaceable. They are manufactured with the same care and precision that goes into our ball bearings. The following are descriptions of the most common types of shields and seals we can supply. Please consult a member of the company's Sales Engineering staff for information on the availability of special designs that may be suited to your specific applications.

## Z \& H Type Shields

"Z" and "H" type shields designate non-contact metal shields. "Z" type shields are the simplest form of closure and, for most bearings, are removable. "H" type shields are similar to "Z" types but are not removable.

It is advantageous to use shields rather than seals in some applications because there are no interacting surfaces to create drag. This results in no appreciable increase in torque or speed limitations and operation can be compared to that of open ball bearings.

## Contact Seals

" $D$ " type seals consist of a molded Buna-N lip seal with an integral steel insert. While this closure type provides excellent sealing characteristics, several factors must be considered for its application. The material normally used on this seal has a maximum continuous operating temperature limit of $250^{\circ} \mathrm{F}$. Although it is impervious to many oils and greases, consideration must be given to lubrication selection. It is also capable of providing a better seal than most other types by increasing the seal lip pressure against the inner ring O.D. This can result in a higher bearing torque than with other type seals and may cause undesirable seal lip heat build-up in high speed applications.

## Non-Contact Seals

"S" type seals are constructed in the same fashion as the "D" type seals. This closure type has the same temperature limitation of $250^{\circ} \mathrm{F}$. It also is impervious to many oils and greases, but the same considerations should be noted on lubrication selection. The " S " type seal is uniquely designed to avoid contact on the inner ring land, significantly reducing torque over the "D" type configuration.
"L" type seals are fabricated from glass re-inforced teflon. When assembled, a very small gap exists between the seal lip and the inner ring O.D. It is common for some contact to occur between these components, resulting in an operating torque increase. The nature of the seal material serves to keep this torque increase to a minimum. In addition, the use of this material allows high operating temperatures with this configuration.

If you have any questions concerning the performance of IBSCO seals in special environments or high speed applications, please contact a member of our Sales Engineering staff.

## ENGINEERING

## Cages

The retainer, also referred to as the cage or separator, is the component part of a ball bearing that separates and positions the balls at approximately equal intervals around the bearing's raceway. The most common cages are shown below. In some cases, such as high-load applications, a full compliment design may be the best choice.

For operating speed, please refer to the Nmax/fn values in the product tables and multiplier table on page 35. IBSCO can also supply specially designed cages to meet your specific requirements. If any doubt, IBSCO should be contacted for optimum cage selection.

## Lubrication

## Lubricant Types

## Oil

Oil is the basic lubricant for ball bearings. Previously most lubricating oil was refined from petroleum. Today, however, synthetic oils such as diesters, silicone polymers, and fluorinated compounds have found acceptance because of improvements in properties. Compared to petroleum base oils, diesters in general have better low temperature properties, lower volatility, and better temperature/viscosity characteristics. Silicones and fluorinated compounds possess even lower volatility and wider temperature/viscosity properties.

Virtually all petroleum and diester oils contain additives that limit chemical changes, protect the metal from corrosion, and improve physical properties.

## Grease

Grease is an oil to which a thickener has been added to prevent oil migration from the lubrication site. It is used in situations where frequent replenishment of the lubricant is undesirable or impossible. All of the oil types mentioned in the next section can be used as grease bases to which are added metallic soaps, synthetic fillers and thickeners. The operative properties of grease depend almost wholly on the base oil. Other factors being equal, the use of grease rather than oil results in higher starting and running torque and can limit the bearing to lower speeds.

## Oils and Base Fluids

## Petroleum Mineral Lubricants

Petroleum lubricants have excellent load carrying abilities and are naturally good against corrosion, but are useable only at moderate temperature ranges ( $-25^{\circ}$ to $250^{\circ} \mathrm{F}$ ). Greases that use petroleum oils for bases have a high dN (in $\mathrm{mm} X$ speed in rpm ) capability. Greases of this type would be recommended for use at moderate temperatures, light to heavy loads and moderate to high speeds.

## Super-Refined Petroleum Lubricants

While these lubricants are usable at higher temperatures than petroleum oils $\left(-65^{\circ}\right.$ to $\left.350^{\circ} \mathrm{F}\right)$, they still exhibit the same excellent load carrying capacity. This further refinement eliminates unwanted properties, leaving only the desired chemical chains. Additives are introduced to increase the oxidation resistance, etc.

## Synthetic Lubricants

The esters, diesters and poly-a-olefins are probably the most common synthetic lubricants. They do not have the film strength capacity of a petroleum product, but do have a wide temperature range $\left(-65^{\circ}\right.$ to $\left.350^{\circ} \mathrm{F}\right)$ and are oxidation resistant.

Synthetic hydrocarbons are finding a greater use in the miniature and instrument ball bearing industry because they have proved to be a superior general purpose lubricant for a variety of speeds, temperatures and environments.

## Silicone Lubricants

Silicone products are useful over a much wider temperature range $\left(-100^{\circ}\right.$ to $\left.400^{\circ} \mathrm{F}\right)$, but do not have the load carrying ability of petroleum types and other synthetics. It has become customary in the instrument and miniature bearing industry, in recent years, to derate the dynamic load rating (Cr) of a bearing to $1 / 3$ of the value shown in this catalog if a silicone product is used.

## Perfluorinated Polyether (PFPE)

Oils and greases of this type have found wide use where stability at extremely high temperatures and/or chemical inertness are required. This specialty lubricant has excellent load carrying capabilities but its inertness makes it less compatible to additives, and less corrosion resistant.

## Solid Film lubricants

Solid film lubricants are any non-fluids used to prevent wear and reduce friction. They can range from simple sacrificial cages to graphite powder and ion sputtering. Each type must be engineered for the specific application.

Solid film lubricants have definite advantages. They are very useful in areas of temperature extremes, vacuum, radiation, pressure or harsh environments where conventional lubricants would fail. In addition, these lubricants do not deteriorate in storage.

Note: The above table details only a handful of the many hundreds of lubricants available from IBSCO.
IBSCO's Clean Room Lubrication Center is constructed and maintained as Class 10,000 @ 0.5 microns, with Class 100 at the bench, certified annually to Federal Standard 209E.
Utilizing the most advanced techniques and equipment, IBSCO's Clean Room Lubrication Center is certified by both New Hampshire Ball Bearing (NHBB) and NMB as a Factory Authorized Re-lubrication Center.

## Lubrication Methods

## Centrifuged Oil

Centrifuging an oil-lubricated bearing removes excess oil and leaves only a very thin film on all surfaces. This method is used on low torque bearings and can be specified for low torque applications.

## Vacuum Impregnation of Cages

Vacuum impregnation, used with ball bearings containing porous cages, forces lubricant into the pores, using the cage as an oil reservoir. hen this method is used with a greased bearing, its purpose is to prevent the cage material from leaching oil from the lubricant. Normally, the base oil of the grease is used in the cage to prevent incompatibility.

## Grease Packing

Grease packing approximately $1 / 4$ to $1 / 3$ of a ball bearing's internal free volume is one of the most common methods of lubrication. Grease quantities are controlled by the use of special lubrication equipment. IBSCO is able to control the amount of lubricant to 0.5 mg if specified.

## Grease Plating

Grease plating consists of mixing a quantity of grease and solvent to the desired consistency, lubricating the bearing with this mixture, then evaporating the solvent at a moderate temperature, leaving a thin film of grease on the raceways, balls and cage. Grease plating is used to lower torque values of grease packed bearings bearings.

## Oil Plating

Oil plating consists of mixing a quantity of oil and solvent to the desired consistency, lubricating the bearing with this mixture, then evaporating the solvent at a moderate temperature, leaving a thin film of oil on the raceways, balls and cage. Oil plating is used to greatly lower torque values of oil lubricated bearings bearings and can be specified for extremely low torque applications.

## Speed Factor

The maximum usable operating speed of a grease lubricant is dependent on the type of base oil. The speed factor is a function of the bore of the bearing (d) in millimeters (mm) and the speed of the bearing $(\mathrm{N})$ in revolutions per minute (RPM) where:
$d N=d$ (bearing bore, $m m) \times N(R P M)$

Table of fn vs Cage, Lubricant Types and Ring Rotating

|  | Metal Cage |  | Phenolic or Polyimide |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 2-Piece or <br> Crown Type | Crown Type |  | Full Section <br> Type |  |  |
| LubricantRing <br> Rotating | Inner | Outer | Inner | Outer | Inner | Outer |
| Setroum Oil | 1.0 | 0.8 | 2.0 | 1.2 | 4.0 | 2.4 |
| Synthetic Oil | 1.0 | 0.8 | 2.0 | 1.2 | 4.0 | 2.4 |
| Silicone Oil | 0.8 | 0.7 | 0.8 | 0.7 | 0.8 | 0.7 |
| Non-Channeling Grease | 1.0 | 0.6 | 1.6 | 1.0 | 1.6 | 1.0 |
| Channeling Grease | 1.0 | 0.8 | 2.0 | 1.2 | 2.4 | 1.6 |
| Silicone Grease | 0.8 | 0.7 | 0.8 | 0.7 | 0.8 | 0.7 |

## Operating Speed

To determine whether a particular bearing will operate satisfactorily at the required speed, multiply that bearing's value (Nmax/fn) by the proper factor taken from the fn vs Cage table shown. Note that the table takes into account lubricant and cage type. When petroleum or synthetic ester oils are used, the maximum speed Nmax is dictated by the ball cage material and design or centrifugal ball loads rather than the lubricant.

For full ball complement types, the listed Nmax values apply regardless of the lubricant type or whether the inner ring or outer ring rotates. For speed limit values Nmax, the Nmax/fn values shown in the product listings must be multiplied by the fn values tabulated above.

| Type | $\mathbf{d N}$ | Temperature Range ${ }^{\circ} \mathrm{F}\left({ }^{\circ} \mathrm{C}\right)$ |
| :--- | :---: | :---: |
| Petroleum | 600,000 | -25 to +250 <br> $(-32$ to +121$)$ |

## ENGINEERING

## Preload and Duplex Ball Bearings

Ball Bearings are preloaded for a variety of reasons:

- To eliminate radial and axial looseness
- To reduce operating noise
- To improve positioning accuracy
- To reduce repetitive runout
- To reduce the possibility of damage from vibratory loading
- To increase life and axial capacity
- To increase stiffness

There are essentially two ways to preload a ball bearing, either by using a spring or through a solid stack of parts.

Spring preloading con consist of a coil spring or a wavy washer which applies a force against the inner or outer ring of the non-interference fitted bearing in the assembly.

Since in a spring the load is fairly consistent over a wide range of compressed length, the use of a spring for preloading eliminates the need for holding tight tolerances on machined parts. For example, retaining rings can be used in the spindle assembly, thus saving the cost of a locating shoulder, shims or threaded members. Normally a spring would not be used where the assembly must withstand reversing thrust loads.

A solid stack method may be used when precise location control is required. For example, as in a precision motor, the use of built-in preload is suggested. Ball bearing with built-in preload are often referred to as duplex ball bearings. When the set of bearings is assembled, the thrust load needed to make the adjacent faces of the rings contact becomes the desired preload. Built-in preload helps satisfy the requirements of increased axial and radial stiffness and deflection control.

There are three methods of mounting preloaded duplex bearings: back-to-back, face-to-face and tandem.

When a back-to-back ( $D B$ ) duplex pair is mounted, the outer rings abut and the inner rings are drawn together, providing maximum stiffness.

## ENGINEERING

## Preload and Duplex Ball Bearings

When face-to-face (DF) duplex pairs are mounted, the inner rings abut and the outer rings are drawn together, providing a higher radial and axial stiffness and accommodation of misalignment.

With tandem (DT) pairs, both inner and outer rings abut and are capable of sharing a thrust load, providing increased thrust capacity.

IBSCO can provide assistance in selecting the appropriate preload specifications for your application.

## ENGINEERING

## Assembly \& Fitting Procedure

The operating characteristics of a system can be drastically affected by the way in which the ball bearings are handled and mounted. A bearing which has been damaged due to excessive force or shock loading during assembly, or which is fitted too tight or too loose, may cause the device to perform in a substandard manner.

By following a few general guidelines during the design of mating parts and by observing some basic cautions in the assembly process, the possibility of producing malfunctioning devices will be considerably reduced.

The chart on the following page lists recommended fits for most normal situations. There are four cautions which must be observed:

1. When establishing shaft or housing sizes, the effect of differential thermal expansion must be accounted for. The Table of Recommended Fits assumes stable operating conditions, so if thermal gradients are known to be present or dissimilar materials are being used, the room temperature fits must be adjusted so that the proper fit is attained at operating temperature. Approximate thermal coefficients for common material are available from IBSCO Applications Engineering staff.
2. When miniature and instrument ball bearings are interference fitted (either intentionally or as a result of thermal gradients) the bearing radial play can be estimated to be reduced by an amount equal to $80 \%$ of the actual diametrical interference fit. This $80 \%$ figure is conservative, but is of good use for design purposes. Depending on the materials involved, this factor will typically range from $50 \%$ to $80 \%$. The following is an example of calculating loss of radial play:

| Radial Play of Bearing: | $.0002 "$ |
| :--- | :--- |
| Total Interference Fit: | .0003 " Tight |
| $80 \%$ of Interference Fit (.0003" x 80\%) | .00024 " |
| Theoretical Resultant Radial Play <br> of Bearing | .00004 " Tight |

Theoretically, this bearing could be operating with negative radial play. A bearing operated in an excessive negative radial play condition will perform with reduced life. However, the above calculation is for design only, and does not take into account housing material, shaft material, or surface finish of the housing or shaft surfaces. As an example, if the finish of the shaft surface is rough, a part of the interference between the inner ring and shaft will be absorbed by the deformation of the shaft surface. This will serve to reduce the overall interference fit, and thus, the radial play of the bearing will not be reduced as much as is shown in the calculation above. If assistance on fits and their effect on
bearing performance is required, please consult a member of IBSCO Applications Engineering staff.

The table of recommended fits is based on the use of bearings of ABEC 5 or better tolerance level.
3. If the outer or inner ring face is to be clamped or abutted against a shoulder, care must be taken to make sure that this shoulder configuration provides a good mounting surface:

- The shoulder face must be perpendicular to the bearing mounting seat. The maximum permissible angle of misalignment is recommended to be $1 / 4^{\circ}$.
- The corner between the mounting diameter and the face must have an undercut or a fillet radius no larger than that shown on the listing page under the column "Fillet Radius r".
- The shoulder diameter must meet the requirements shown on the table of recommended shoulder diameters.

4. Assembly technique is extremely critical. After the design is finalized and assembly procedures are being formulated, the bearing Static Capacity - Cor - becomes extremely important. It is easy, for instance, to exceed the 3 pound capacity of a SR09 during assembly. After assembly to the shaft, damage can be done either by direct pressure or by moment load while the bearing-and-shaft subassembly is being forced into a tight housing. A few simple calculations will underscore this point.

Adequate fixturing should always be provided for handling and assembling precision bearings. This fixturing must be designed so that, when assembling the bearing to the shaft, force is applied only to the inner ring, and, when assembling into the housing, force is applied only to the outer ring. Further, the fixturing must preclude the application of any moment or shock loads which would be transmitted through the bearing. Careful attention to this assembly phase of the total design effort can prevent many problems and provide savings when production starts. You will find our engineers eager to help in this, one of the most important phases of taking a product from design to the marketplace.

## Miniature \& Instrument Bearings

Detailed in this catalog, IBSCO is the largest Authorized Distributor for both NMB and NHBB miniature \& Instrument ball bearings. IBSCO inventories vast stocks at all times, in virtually every configuration.

## Machine Tool Spindle Bearings

Radial or angular contact high-speed, super precision, phenolic retainer machine tool spindle bearings. Manufactured in ABEC's 5, 7 and 9, and available with optional ceramic balls.

## Stainless Steel Bearings

IBSCO maintains one of the worlds most complete inventories of precision bearings in 400 series stainless steel, as well as NMB's proprietary "DD" stainless steel.

## Bearing Re-Iubrication

As an Authorized Lubrication Center for both NMB and NHBB, with hundreds of specialty lubricants in stock, IBSCO's clean room re-lubrication facility is certified annually to Federal Standard 209.

## ISO 9001 Quality

A forerunner in the quality arena, IBSCO is ISO9001 certified. Our commitment to quality is how IBSCO is able to maintain a customer satisfaction index of $99.7 \%$.

## NHBB Bearings

IBSCO is the largest Authorized Distributor for New Hampshire Ball Bearing miniature and instrument bearings, as well as being an NHBB Authorized Lubrication Center.

Thin Section \& Torque Tube Bearings
Thin and Extra Thin section bearings are available in inch or metric sizes, in chrome or stainless steel. These ranges are also available with phenolic cages for high speed applications, and with extended inner rings.

## Electric Motor Bearings

Electric motor quality bearings, in inch or metric sizes, lubricated to meet your specific needs. This series of bearings exhibit the low noise and vibration levels required in electric motor applications.

## Needle and Linear Bearings \& Slides

INA, IKO, NB \& THK brand needle and linear bearings and slides, including miniature sizes. IBSCO can custom lubricate this product range to meet the low vacuum environment present in chip manufacturing.

## Medical and Dental Bearings

IBSCO is a major supplier of high speed bearings for medical and dental applications. NHBB high speed bearings can sustain speeds of 500,000 rpm! Even faster with optional ceramic balls.

## Precision Mechanical Assemblies

Speed up and improve production with high quality custom designed rotating mechanical assemblies. These cost saving solutions eliminate tolerance stack up and control runouts, while reducing inventory items.

NMB Bearings
IBSCO is the largest Authorized Distributor for NMB brand miniature and instrument bearings. With factories in Japan, Thailand and Singapore, NMB bearings are unequaled for quality \& value.
